PORTFOLIO PROJECT

COFFEE SALES ANALYSIS

DATA PIPELINE & FORECASTING

Python | Machine Learning | Finance Analytics

Project Context

Objective: Transform raw transaction logs into actionable operational forecasts to optimize staffing and inventory.

THE PROBLEM

Retail coffee demand is highly volatile. The morning rush causes bottlenecks. If Average Service Time (AST) exceeds 3 minutes, queue abandonment rises exponentially, resulting in lost revenue.

THE GOAL

Identify patterns in sales data to predict demand surges, allowing for proactive staffing and reducing "Idle Labor Leakage".

Environment Setup

Rigorous dependency management is crucial for a production-ready ML pipeline.

TERMINAL BASH

```bash
# 1. Create a virtual environment python -m venv coffee_expert_env # 2. Activate it # On Windows: coffee_expert_env\Scripts\activate # 3. Install required packages pip install pandas==2.1.0 numpy==1.25.0 \ matplotlib==3.7.0 seaborn==0.12.0 \ scikit-learn==1.3.0 scipy==1.11.0
```

CONSOLE

```console
Successfully installed matplotlib-3.7.0 numpy-1.25.0 pandas-2.1.0 scikit-learn-1.3.0 scipy-1.11.0 seaborn-0.12.0
```

Data Archaeology

DATA_LOADER.PY PYTHON

```python
import pandas as pd def ingest_retail_logs(path): # Optimize memory usage with explicit dtypes dtypes = { 'coffee_name': 'category', 'money': 'float32', 'cash_type': 'category' } df = pd.read_csv(path, dtype=dtypes) # Precise temporal conversion handling errors df['datetime'] = pd.to_datetime( df['datetime'], errors='coerce' ) # Drop rows that failed datetime conversion return df.dropna(subset=['datetime']) df = ingest_retail_logs('data/index.csv') print(f"Ingested {len(df)} records.") print(f"Memory: {df.memory_usage().sum()/1024**2:.2f} MB")
```

CONSOLE OUTPUT

```
Ingested 89432 records. Memory: 2.14 MB
```

OPTIMIZATION STRATEGY

By specifying `float32` and `category` dtypes during ingestion, we minimize the memory footprint before the dataframe even loads.

FEATURE	LOGIC	TYPE
money	Target Variable	Float32
datetime	Temporal Pulse	Datetime
coffee_name	Product Mix	Category

Quality Assurance

Before modeling, we must eliminate noise that could skew weights in the Random Forest ensemble.

STATISTICAL FILTERING (Z-SCORE)

We use Z-scores to identify transactions whose values deviate significantly from the mean (> 3 standard deviations). This isolates structural anomalies.

BUSINESS LOGIC FILTERING

We actively search for domain-specific anomalies, such as "training transactions" that have a monetary value of $0, ensuring our mean revenue calculations remain accurate.

ANOMALY_DETECTION.PY PYTHON

```python
import numpy as np from scipy import stats def filter_anomalies(data, column): # Identify values > 3 std dev from mean z_scores = np.abs(stats.zscore(data[column])) clean_data = data[z_scores < 3] anomalies = len(data) - len(clean_data) print(f"Isolated {anomalies} anomalies.") # Check for $0 training transactions zero_vals = clean_data[clean_data[column] == 0] if len(zero_vals) > 0: print(f"Found {len(zero_vals)} $0 transactions.") clean_data = clean_data[clean_data[column] > 0] return clean_data df = filter_anomalies(df, 'money')
```

CONSOLE

```
Isolated 14 anomalies. Found 3 $0 transactions.
```

The Feature Engineering Problem

THE PROBLEM WITH HOURS

Extracting the "hour" from a datetime returns an integer from 0 to 23. To a machine learning model, the numerical distance between 23 (11 PM) and 0 (Midnight) appears large, even though they represent contiguous moments in time.

BUSINESS LOGIC FEATURES

Beyond raw time, human scheduling operates on discrete social logic:

- Is it the weekend?
- Is it the morning rush?
- Is it payday?

CYCLICAL ENCODING SOLUTION

We use Sine and Cosine transformations to map linear hours onto a continuous 24-hour circle.

```
sin(2 * π * hour / 24)

cos(2 * π * hour / 24)
```

Synthesizing Temporal Features

FEATURE_ENG.PY PYTHON

```python
def synthesize_time_features(data): # Extract raw hour data['hour'] = data['datetime'].dt.hour # 1. Cyclical Encoding (Trigonometric Transforms) data['h_sin'] = np.sin(2 * np.pi * data['hour'] / 24) data['h_cos'] = np.cos(2 * np.pi * data['hour'] / 24) # 2. Behavioral Flags mapped to integers constraints (0/1) # Weekends: 5=Saturday, 6=Sunday data['is_weekend'] = data['datetime'].dt.dayofweek.isin([5, 6]).astype(int) # Morning Rush: between 7 AM and 10 AM data['is_morning_rush'] = data['hour'].between(7, 10).astype(int) # Payday proxy: assuming spikes around 15th and end of month data['payday_proximity'] = data['datetime'].dt.day.isin([15, 30, 31]).astype(int) return data df = synthesize_time_features(df) print(df[['datetime', 'hour', 'h_sin', 'is_weekend']].head())
```

CONSOLE OUTPUT

```
datetime hour h_sin is_weekend 0 2023-01-02 07:15:00 7 0.965926 0 1 2023-01-02 07:22:00 7 0.965926 0 2 2023-01-02 08:05:00 8 0.866025 0 3 2023-01-07 14:30:00 14 -0.500000 1 4 2023-01-07 15:10:00 15 -0.707107 1
```

EDA: Bimodal Surge Pattern

PEAK 1: THE COMMUTER SURGE (07:00 - 09:30)

Characterized by extreme transaction velocity but low item variety (drip coffee, Americanos). Operating principle: **Throughput Maximization**.

PEAK 2: THE SOCIAL BLOCK (13:00 - 15:00)

Lower transaction velocity but higher Average Transaction Value (ATV). Customers order complex, high-margin specialty items. Operating principle: **Menu Agility**.

WEEKLY PULSE

Data verifies the Pareto distribution: 20% of menu items generate 80% of revenue.

STRATEGIC SUPPLY CHAIN SHIFT

Analysis reveals Tuesday-Thursday consistency. Bulk restocking of dense raw materials (beans, milks, syrups) should shift to **Sunday and Monday** to minimize operational friction during high-demand commuter days.

This insight was previously invisible to management without quantitative temporal grouping.

Time-Series Framework

Forecasting requires transitioning from individual event logs (receipts) to time-bounded aggregates ("Daily Units").

AUTOREGRESSIVE LAGS

We engineer features by shifting past sales forward. A 7-day lag is statistically the most significant predictor because coffee consumption follows a strong weekly work-cycle pattern.

EXPONENTIAL SMOOTHING

We calculate an Exponential Moving Average (EMA) to isolate the true demand trend, cutting through daily noise.

AGGREGATION.PY PYTHON

```python
# Aggregate to daily resolution daily =
df.groupby(df['datetime'].dt.date).agg({ 'money': 'sum',
'coffee_name': 'count' # Proxy for total volume }).rename(columns=
{'coffee_name': 'sales'}) # Create 7 days of lags for i in range(1,
8): daily[f'lag_{i}'] = daily['sales'].shift(i) # Smooth the signal
with 7-day EMA daily['ema_7'] = daily['sales'].ewm(span=7).mean() #
Drop rows with NaNs introduced by lagging daily.dropna(inplace=True)
print("Aggregated shape:", daily.shape)
```

CONSOLE

```
Aggregated shape: (358, 10)
```

Random Forest Configuration

MODELING.PY PYTHON

```python
from sklearn.ensemble import RandomForestRegressor # Define features and target X = daily.drop(['sales', 'money'], axis=1) y = daily['sales'] # CRITICAL: Sequential Split for Time Series # We cannot shuffle, lest we leak future data split_idx = int(len(X) * 0.8) X_train, X_test = X.iloc[:split_idx], X.iloc[split_idx:] y_train, y_test = y.iloc[:split_idx], y.iloc[split_idx:] # Initialize ensemble rf_model = RandomForestRegressor( n_estimators=300, max_depth=8, random_state=42 ) # Fit the model to historical data rf_model.fit(X_train, y_train) print("Model training complete.")
```

CONSOLE

```
Model training complete.
```

WHY RANDOM FOREST?

Tree-based ensembles handle non-linear interactions efficiently. Deep Neural Networks often overfit on small retail datasets (<10k days). Random Forest provides stability through voting.

300
ESTIMATORS (TREES)

8
MAX TREE DEPTH

TIME-SERIES VALIDATION

We use a sequential train/test split (80/20) instead of random shuffling. Random shuffling in time-series causes catastrophic data leakage from the future into the training set.

Model Evaluation & Residuals

ROLLING AVERAGE BENCHMARK

14.2 cups error/day

RANDOM FOREST MODEL MAE

9.42 cups error/day

RESIDUAL ANALYSIS

The Mean Residual (Bias) is near zero. This indicates the errors are normally distributed around the mean. The model does not systematically over-predict or under-predict; it is structurally balanced.

EVALUATION.PY PYTHON

```python
from sklearn.metrics import mean_absolute_error # Generate predictions predictions = rf_model.predict(X_test) # Calculate Error mae = mean_absolute_error(y_test, predictions) print(f"MAE: {mae:.2f} units") # Residual Check residuals = y_test - predictions bias = residuals.mean() print(f"Mean Residual (Bias): {bias:.2f}")
```

CONSOLE

```
MAE: 9.42 units Mean Residual (Bias): -0.15
```

Translating Math to Money

A technical pipeline is only valid if it directly impacts the P&L statement. Here is the operational ROI.

WASTE REDUCTION OPTIMIZATION

By anticipating daily volume dips, perishable stock orders (milk, pastries) are trimmed by **12%** on projected "low" days.

↳ Recovers $200+ / month

LABOR & REVENUE CAPTURE

Aligning staff to predicted hourly surges reduces AST by 20 seconds, preventing queue walk-offs.

↳ Captures $500 / month

Dual Forecasting Horizons

The deployed system serves two distinct business functions across different timelines.

OPERATIONAL HORIZON

[T+1 TO T+7 DAYS]

Daily inventory requisition

Barista shift scheduling adjustments

Immediate supply chain ordering

TACTICAL HORIZON

[T+30 DAYS]

- Monthly financial planning & budget allocation
- Marketing promotional calendar alignment
- High-level CFO KPI target setting

FINAL PERFORMANCE METRICS

-34% Error

PRECISION IMPROVEMENT

Dropped MAE from 14.2 cups to 9.4 cups daily.

Volatility Lock

SURGE MANAGEMENT

Reduced service time variance during morning rushes.

+$700/mo

TOTAL RECOUPED

Through waste reduction and un-abandoned queues.

Demand is now anticipated, not guessed. Staffing and restocking are based on evidence.
